#### 4.4-3

Use a recursion tree to determine a good asymptotic upper bound on the recurrence T(n) = 4T(n/2 + 2) + n. Use the substitution method to verify your answer.

#### 4.4-4

Use a recursion tree to determine a good asymptotic upper bound on the recurrence T(n) = 2T(n-1) + 1. Use the substitution method to verify your answer.

#### 4.4-5

Use a recursion tree to determine a good asymptotic upper bound on the recurrence T(n) = T(n-1) + T(n/2) + n. Use the substitution method to verify your answer.

#### 4.4-6

Argue that the solution to the recurrence T(n) = T(n/3) + T(2n/3) + cn, where c is a constant, is  $\Omega(n \lg n)$  by appealing to a recursion tree.

# 4.4-7

Draw the recursion tree for  $T(n) = 4T(\lfloor n/2 \rfloor) + cn$ , where c is a constant, and provide a tight asymptotic bound on its solution. Verify your bound by the substitution method.

#### 4.4-8

Use a recursion tree to give an asymptotically tight solution to the recurrence T(n) = T(n-a) + T(a) + cn, where  $a \ge 1$  and c > 0 are constants.

#### 4.4-9

Use a recursion tree to give an asymptotically tight solution to the recurrence  $T(n) = T(\alpha n) + T((1-\alpha)n) + cn$ , where  $\alpha$  is a constant in the range  $0 < \alpha < 1$  and c > 0 is also a constant.

# **4.5** The master method for solving recurrences

The master method provides a "cookbook" method for solving recurrences of the form

$$T(n) = aT(n/b) + f(n),$$
 (4.20)

where  $a \ge 1$  and b > 1 are constants and f(n) is an asymptotically positive function. To use the master method, you will need to memorize three cases, but then you will be able to solve many recurrences quite easily, often without pencil and paper.

The recurrence (4.20) describes the running time of an algorithm that divides a problem of size n into a subproblems, each of size n/b, where a and b are positive constants. The a subproblems are solved recursively, each in time T(n/b). The function f(n) encompasses the cost of dividing the problem and combining the results of the subproblems. For example, the recurrence arising from Strassen's algorithm has a = 7, b = 2, and  $f(n) = \Theta(n^2)$ .

As a matter of technical correctness, the recurrence is not actually well defined, because n/b might not be an integer. Replacing each of the a terms T(n/b) with either  $T(\lfloor n/b \rfloor)$  or  $T(\lceil n/b \rceil)$  will not affect the asymptotic behavior of the recurrence, however. (We will prove this assertion in the next section.) We normally find it convenient, therefore, to omit the floor and ceiling functions when writing divide-and-conquer recurrences of this form.

#### The master theorem

The master method depends on the following theorem.

# Theorem 4.1 (Master theorem)

Let  $a \ge 1$  and b > 1 be constants, let f(n) be a function, and let T(n) be defined on the nonnegative integers by the recurrence

$$T(n) = aT(n/b) + f(n) ,$$

where we interpret n/b to mean either  $\lfloor n/b \rfloor$  or  $\lceil n/b \rceil$ . Then T(n) has the following asymptotic bounds:

- 1. If  $f(n) = O(n^{\log_b a \epsilon})$  for some constant  $\epsilon > 0$ , then  $T(n) = \Theta(n^{\log_b a})$ .
- 2. If  $f(n) = \Theta(n^{\log_b a})$ , then  $T(n) = \Theta(n^{\log_b a} \lg n)$ .
- 3. If  $f(n) = \Omega(n^{\log_b a + \epsilon})$  for some constant  $\epsilon > 0$ , and if  $af(n/b) \le cf(n)$  for some constant c < 1 and all sufficiently large n, then  $T(n) = \Theta(f(n))$ .

Before applying the master theorem to some examples, let's spend a moment trying to understand what it says. In each of the three cases, we compare the function f(n) with the function  $n^{\log_b a}$ . Intuitively, the larger of the two functions determines the solution to the recurrence. If, as in case 1, the function  $n^{\log_b a}$  is the larger, then the solution is  $T(n) = \Theta(n^{\log_b a})$ . If, as in case 3, the function f(n) is the larger, then the solution is  $T(n) = \Theta(f(n))$ . If, as in case 2, the two functions are the same size, we multiply by a logarithmic factor, and the solution is  $T(n) = \Theta(n^{\log_b a} \log_b a) = \Theta(f(n) \log_b a)$ .

Beyond this intuition, you need to be aware of some technicalities. In the first case, not only must f(n) be smaller than  $n^{\log_b a}$ , it must be *polynomially* smaller.

That is, f(n) must be asymptotically smaller than  $n^{\log_b a}$  by a factor of  $n^{\epsilon}$  for some constant  $\epsilon > 0$ . In the third case, not only must f(n) be larger than  $n^{\log_b a}$ , it also must be polynomially larger and in addition satisfy the "regularity" condition that  $af(n/b) \leq cf(n)$ . This condition is satisfied by most of the polynomially bounded functions that we shall encounter.

Note that the three cases do not cover all the possibilities for f(n). There is a gap between cases 1 and 2 when f(n) is smaller than  $n^{\log_b a}$  but not polynomially smaller. Similarly, there is a gap between cases 2 and 3 when f(n) is larger than  $n^{\log_b a}$  but not polynomially larger. If the function f(n) falls into one of these gaps, or if the regularity condition in case 3 fails to hold, you cannot use the master method to solve the recurrence.

# Using the master method

To use the master method, we simply determine which case (if any) of the master theorem applies and write down the answer.

As a first example, consider

$$T(n) = 9T(n/3) + n.$$

For this recurrence, we have a=9, b=3, f(n)=n, and thus we have that  $n^{\log_b a}=n^{\log_3 9}=\Theta(n^2)$ . Since  $f(n)=O(n^{\log_3 9-\epsilon})$ , where  $\epsilon=1$ , we can apply case 1 of the master theorem and conclude that the solution is  $T(n)=\Theta(n^2)$ .

Now consider

$$T(n) = T(2n/3) + 1,$$

in which a=1, b=3/2, f(n)=1, and  $n^{\log_b a}=n^{\log_{3/2} 1}=n^0=1$ . Case 2 applies, since  $f(n)=\Theta(n^{\log_b a})=\Theta(1)$ , and thus the solution to the recurrence is  $T(n)=\Theta(\lg n)$ .

For the recurrence

$$T(n) = 3T(n/4) + n \lg n ,$$

we have a=3, b=4,  $f(n)=n\lg n$ , and  $n^{\log_b a}=n^{\log_4 3}=O(n^{0.793})$ . Since  $f(n)=\Omega(n^{\log_4 3+\epsilon})$ , where  $\epsilon\approx 0.2$ , case 3 applies if we can show that the regularity condition holds for f(n). For sufficiently large n, we have that  $af(n/b)=3(n/4)\lg(n/4)\leq (3/4)n\lg n=cf(n)$  for c=3/4. Consequently, by case 3, the solution to the recurrence is  $T(n)=\Theta(n\lg n)$ .

The master method does not apply to the recurrence

$$T(n) = 2T(n/2) + n \lg n ,$$

even though it appears to have the proper form: a = 2, b = 2,  $f(n) = n \lg n$ , and  $n^{\log_b a} = n$ . You might mistakenly think that case 3 should apply, since

 $f(n) = n \lg n$  is asymptotically larger than  $n^{\log_b a} = n$ . The problem is that it is not *polynomially* larger. The ratio  $f(n)/n^{\log_b a} = (n \lg n)/n = \lg n$  is asymptotically less than  $n^{\epsilon}$  for any positive constant  $\epsilon$ . Consequently, the recurrence falls into the gap between case 2 and case 3. (See Exercise 4.6-2 for a solution.)

Let's use the master method to solve the recurrences we saw in Sections 4.1 and 4.2. Recurrence (4.7),

$$T(n) = 2T(n/2) + \Theta(n) ,$$

characterizes the running times of the divide-and-conquer algorithm for both the maximum-subarray problem and merge sort. (As is our practice, we omit stating the base case in the recurrence.) Here, we have a=2, b=2,  $f(n)=\Theta(n)$ , and thus we have that  $n^{\log_b a}=n^{\log_2 2}=n$ . Case 2 applies, since  $f(n)=\Theta(n)$ , and so we have the solution  $T(n)=\Theta(n \lg n)$ .

Recurrence (4.17),

$$T(n) = 8T(n/2) + \Theta(n^2),$$

describes the running time of the first divide-and-conquer algorithm that we saw for matrix multiplication. Now we have a=8, b=2, and  $f(n)=\Theta(n^2)$ , and so  $n^{\log_b a}=n^{\log_2 8}=n^3$ . Since  $n^3$  is polynomially larger than f(n) (that is,  $f(n)=O(n^{3-\epsilon})$  for  $\epsilon=1$ ), case 1 applies, and  $T(n)=\Theta(n^3)$ . Finally, consider recurrence (4.18),

$$T(n) = 7T(n/2) + \Theta(n^2) ,$$

which describes the running time of Strassen's algorithm. Here, we have a=7, b=2,  $f(n)=\Theta(n^2)$ , and thus  $n^{\log_b a}=n^{\log_2 7}$ . Rewriting  $\log_2 7$  as  $\lg 7$  and recalling that  $2.80 < \lg 7 < 2.81$ , we see that  $f(n)=O(n^{\lg 7-\epsilon})$  for  $\epsilon=0.8$ . Again, case 1 applies, and we have the solution  $T(n)=\Theta(n^{\lg 7})$ .

#### **Exercises**

# 4.5-1

Use the master method to give tight asymptotic bounds for the following recurrences.

a. 
$$T(n) = 2T(n/4) + 1$$
.

**b.** 
$$T(n) = 2T(n/4) + \sqrt{n}$$
.

c. 
$$T(n) = 2T(n/4) + n$$
.

**d.** 
$$T(n) = 2T(n/4) + n^2$$
.

#### 4.5-2

Professor Caesar wishes to develop a matrix-multiplication algorithm that is asymptotically faster than Strassen's algorithm. His algorithm will use the divide-and-conquer method, dividing each matrix into pieces of size  $n/4 \times n/4$ , and the divide and combine steps together will take  $\Theta(n^2)$  time. He needs to determine how many subproblems his algorithm has to create in order to beat Strassen's algorithm. If his algorithm creates a subproblems, then the recurrence for the running time T(n) becomes  $T(n) = aT(n/4) + \Theta(n^2)$ . What is the largest integer value of a for which Professor Caesar's algorithm would be asymptotically faster than Strassen's algorithm?

#### 4.5-3

Use the master method to show that the solution to the binary-search recurrence  $T(n) = T(n/2) + \Theta(1)$  is  $T(n) = \Theta(\lg n)$ . (See Exercise 2.3-5 for a description of binary search.)

#### 4.5-4

Can the master method be applied to the recurrence  $T(n) = 4T(n/2) + n^2 \lg n$ ? Why or why not? Give an asymptotic upper bound for this recurrence.

#### 4.5-5 \*

Consider the regularity condition  $af(n/b) \le cf(n)$  for some constant c < 1, which is part of case 3 of the master theorem. Give an example of constants  $a \ge 1$  and b > 1 and a function f(n) that satisfies all the conditions in case 3 of the master theorem except the regularity condition.

## **★** 4.6 Proof of the master theorem

This section contains a proof of the master theorem (Theorem 4.1). You do not need to understand the proof in order to apply the master theorem.

The proof appears in two parts. The first part analyzes the master recurrence (4.20), under the simplifying assumption that T(n) is defined only on exact powers of b > 1, that is, for  $n = 1, b, b^2, \ldots$ . This part gives all the intuition needed to understand why the master theorem is true. The second part shows how to extend the analysis to all positive integers n; it applies mathematical technique to the problem of handling floors and ceilings.

In this section, we shall sometimes abuse our asymptotic notation slightly by using it to describe the behavior of functions that are defined only over exact powers of b. Recall that the definitions of asymptotic notations require that

bounds be proved for all sufficiently large numbers, not just those that are powers of b. Since we could make new asymptotic notations that apply only to the set  $\{b^i: i=0,1,2,\ldots\}$ , instead of to the nonnegative numbers, this abuse is minor.

Nevertheless, we must always be on guard when we use asymptotic notation over a limited domain lest we draw improper conclusions. For example, proving that T(n) = O(n) when n is an exact power of 2 does not guarantee that T(n) = O(n). The function T(n) could be defined as

$$T(n) = \begin{cases} n & \text{if } n = 1, 2, 4, 8, \dots, \\ n^2 & \text{otherwise} \end{cases}$$

in which case the best upper bound that applies to all values of n is  $T(n) = O(n^2)$ . Because of this sort of drastic consequence, we shall never use asymptotic notation over a limited domain without making it absolutely clear from the context that we are doing so.

# 4.6.1 The proof for exact powers

The first part of the proof of the master theorem analyzes the recurrence (4.20)

$$T(n) = aT(n/b) + f(n),$$

for the master method, under the assumption that n is an exact power of b > 1, where b need not be an integer. We break the analysis into three lemmas. The first reduces the problem of solving the master recurrence to the problem of evaluating an expression that contains a summation. The second determines bounds on this summation. The third lemma puts the first two together to prove a version of the master theorem for the case in which n is an exact power of b.

## Lemma 4.2

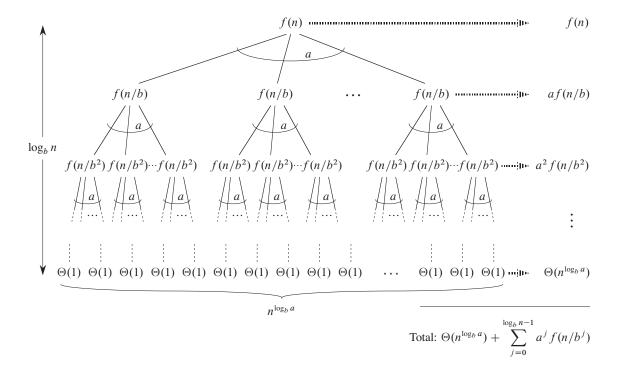

Let  $a \ge 1$  and b > 1 be constants, and let f(n) be a nonnegative function defined on exact powers of b. Define T(n) on exact powers of b by the recurrence

$$T(n) = \begin{cases} \Theta(1) & \text{if } n = 1, \\ aT(n/b) + f(n) & \text{if } n = b^i, \end{cases}$$

where i is a positive integer. Then

$$T(n) = \Theta(n^{\log_b a}) + \sum_{j=0}^{\log_b n - 1} a^j f(n/b^j).$$
 (4.21)

**Proof** We use the recursion tree in Figure 4.7. The root of the tree has cost f(n), and it has a children, each with cost f(n/b). (It is convenient to think of a as being

**Figure 4.7** The recursion tree generated by T(n) = aT(n/b) + f(n). The tree is a complete a-ary tree with  $n^{\log_b a}$  leaves and height  $\log_b n$ . The cost of the nodes at each depth is shown at the right, and their sum is given in equation (4.21).

an integer, especially when visualizing the recursion tree, but the mathematics does not require it.) Each of these children has a children, making  $a^2$  nodes at depth 2, and each of the a children has cost  $f(n/b^2)$ . In general, there are  $a^j$  nodes at depth j, and each has cost  $f(n/b^j)$ . The cost of each leaf is  $T(1) = \Theta(1)$ , and each leaf is at depth  $\log_b n$ , since  $n/b^{\log_b n} = 1$ . There are  $a^{\log_b n} = n^{\log_b a}$  leaves in the tree.

We can obtain equation (4.21) by summing the costs of the nodes at each depth in the tree, as shown in the figure. The cost for all internal nodes at depth j is  $a^{j} f(n/b^{j})$ , and so the total cost of all internal nodes is

$$\sum_{j=0}^{\log_b n-1} a^j f(n/b^j) .$$

In the underlying divide-and-conquer algorithm, this sum represents the costs of dividing problems into subproblems and then recombining the subproblems. The

cost of all the leaves, which is the cost of doing all  $n^{\log_b a}$  subproblems of size 1, is  $\Theta(n^{\log_b a})$ .

In terms of the recursion tree, the three cases of the master theorem correspond to cases in which the total cost of the tree is (1) dominated by the costs in the leaves, (2) evenly distributed among the levels of the tree, or (3) dominated by the cost of the root.

The summation in equation (4.21) describes the cost of the dividing and combining steps in the underlying divide-and-conquer algorithm. The next lemma provides asymptotic bounds on the summation's growth.

#### Lemma 4.3

Let  $a \ge 1$  and b > 1 be constants, and let f(n) be a nonnegative function defined on exact powers of b. A function g(n) defined over exact powers of b by

$$g(n) = \sum_{j=0}^{\log_b n - 1} a^j f(n/b^j)$$
 (4.22)

has the following asymptotic bounds for exact powers of b:

- 1. If  $f(n) = O(n^{\log_b a \epsilon})$  for some constant  $\epsilon > 0$ , then  $g(n) = O(n^{\log_b a})$ .
- 2. If  $f(n) = \Theta(n^{\log_b a})$ , then  $g(n) = \Theta(n^{\log_b a} \lg n)$ .
- 3. If  $af(n/b) \le cf(n)$  for some constant c < 1 and for all sufficiently large n, then  $g(n) = \Theta(f(n))$ .

**Proof** For case 1, we have  $f(n) = O(n^{\log_b a - \epsilon})$ , which implies that  $f(n/b^j) = O((n/b^j)^{\log_b a - \epsilon})$ . Substituting into equation (4.22) yields

$$g(n) = O\left(\sum_{j=0}^{\log_b n - 1} a^j \left(\frac{n}{b^j}\right)^{\log_b a - \epsilon}\right). \tag{4.23}$$

We bound the summation within the *O*-notation by factoring out terms and simplifying, which leaves an increasing geometric series:

$$\sum_{j=0}^{\log_b n-1} a^j \left(\frac{n}{b^j}\right)^{\log_b a - \epsilon} = n^{\log_b a - \epsilon} \sum_{j=0}^{\log_b n-1} \left(\frac{ab^{\epsilon}}{b^{\log_b a}}\right)^j$$
$$= n^{\log_b a - \epsilon} \sum_{j=0}^{\log_b n-1} (b^{\epsilon})^j$$
$$= n^{\log_b a - \epsilon} \left(\frac{b^{\epsilon \log_b n} - 1}{b^{\epsilon} - 1}\right)$$

$$= n^{\log_b a - \epsilon} \left( \frac{n^{\epsilon} - 1}{b^{\epsilon} - 1} \right) .$$

Since b and  $\epsilon$  are constants, we can rewrite the last expression as  $n^{\log_b a - \epsilon} O(n^{\epsilon}) = O(n^{\log_b a})$ . Substituting this expression for the summation in equation (4.23) yields

$$g(n) = O(n^{\log_b a}),$$

thereby proving case 1.

Because case 2 assumes that  $f(n) = \Theta(n^{\log_b a})$ , we have that  $f(n/b^j) = \Theta((n/b^j)^{\log_b a})$ . Substituting into equation (4.22) yields

$$g(n) = \Theta\left(\sum_{j=0}^{\log_b n - 1} a^j \left(\frac{n}{b^j}\right)^{\log_b a}\right). \tag{4.24}$$

We bound the summation within the  $\Theta$ -notation as in case 1, but this time we do not obtain a geometric series. Instead, we discover that every term of the summation is the same:

$$\sum_{j=0}^{\log_b n-1} a^j \left(\frac{n}{b^j}\right)^{\log_b a} = n^{\log_b a} \sum_{j=0}^{\log_b n-1} \left(\frac{a}{b^{\log_b a}}\right)^j$$
$$= n^{\log_b a} \sum_{j=0}^{\log_b n-1} 1$$
$$= n^{\log_b a} \log_b n.$$

Substituting this expression for the summation in equation (4.24) yields

$$g(n) = \Theta(n^{\log_b a} \log_b n)$$
  
=  $\Theta(n^{\log_b a} \log_b n)$ ,

proving case 2.

We prove case 3 similarly. Since f(n) appears in the definition (4.22) of g(n) and all terms of g(n) are nonnegative, we can conclude that  $g(n) = \Omega(f(n))$  for exact powers of b. We assume in the statement of the lemma that  $af(n/b) \le cf(n)$  for some constant c < 1 and all sufficiently large n. We rewrite this assumption as  $f(n/b) \le (c/a) f(n)$  and iterate j times, yielding  $f(n/b^j) \le (c/a)^j f(n)$  or, equivalently,  $a^j f(n/b^j) \le c^j f(n)$ , where we assume that the values we iterate on are sufficiently large. Since the last, and smallest, such value is  $n/b^{j-1}$ , it is enough to assume that  $n/b^{j-1}$  is sufficiently large.

Substituting into equation (4.22) and simplifying yields a geometric series, but unlike the series in case 1, this one has decreasing terms. We use an O(1) term to

capture the terms that are not covered by our assumption that *n* is sufficiently large:

$$g(n) = \sum_{j=0}^{\log_b n-1} a^j f(n/b^j)$$

$$\leq \sum_{j=0}^{\log_b n-1} c^j f(n) + O(1)$$

$$\leq f(n) \sum_{j=0}^{\infty} c^j + O(1)$$

$$= f(n) \left(\frac{1}{1-c}\right) + O(1)$$

$$= O(f(n)),$$

since c is a constant. Thus, we can conclude that  $g(n) = \Theta(f(n))$  for exact powers of b. With case 3 proved, the proof of the lemma is complete.

We can now prove a version of the master theorem for the case in which n is an exact power of b.

#### Lemma 4.4

Let  $a \ge 1$  and b > 1 be constants, and let f(n) be a nonnegative function defined on exact powers of b. Define T(n) on exact powers of b by the recurrence

$$T(n) = \begin{cases} \Theta(1) & \text{if } n = 1, \\ aT(n/b) + f(n) & \text{if } n = b^i, \end{cases}$$

where i is a positive integer. Then T(n) has the following asymptotic bounds for exact powers of b:

- 1. If  $f(n) = O(n^{\log_b a \epsilon})$  for some constant  $\epsilon > 0$ , then  $T(n) = \Theta(n^{\log_b a})$ .
- 2. If  $f(n) = \Theta(n^{\log_b a})$ , then  $T(n) = \Theta(n^{\log_b a} \lg n)$ .
- 3. If  $f(n) = \Omega(n^{\log_b a + \epsilon})$  for some constant  $\epsilon > 0$ , and if  $af(n/b) \le cf(n)$  for some constant c < 1 and all sufficiently large n, then  $T(n) = \Theta(f(n))$ .

**Proof** We use the bounds in Lemma 4.3 to evaluate the summation (4.21) from Lemma 4.2. For case 1, we have

$$T(n) = \Theta(n^{\log_b a}) + O(n^{\log_b a})$$
  
=  $\Theta(n^{\log_b a})$ ,

and for case 2,

$$T(n) = \Theta(n^{\log_b a}) + \Theta(n^{\log_b a} \lg n)$$
  
=  $\Theta(n^{\log_b a} \lg n)$ .

For case 3,

$$T(n) = \Theta(n^{\log_b a}) + \Theta(f(n))$$
$$= \Theta(f(n)),$$

because 
$$f(n) = \Omega(n^{\log_b a + \epsilon})$$
.

# 4.6.2 Floors and ceilings

To complete the proof of the master theorem, we must now extend our analysis to the situation in which floors and ceilings appear in the master recurrence, so that the recurrence is defined for all integers, not for just exact powers of b. Obtaining a lower bound on

$$T(n) = aT(\lceil n/b \rceil) + f(n) \tag{4.25}$$

and an upper bound on

$$T(n) = aT(\lfloor n/b \rfloor) + f(n) \tag{4.26}$$

is routine, since we can push through the bound  $\lceil n/b \rceil \ge n/b$  in the first case to yield the desired result, and we can push through the bound  $\lfloor n/b \rfloor \le n/b$  in the second case. We use much the same technique to lower-bound the recurrence (4.26) as to upper-bound the recurrence (4.25), and so we shall present only this latter bound.

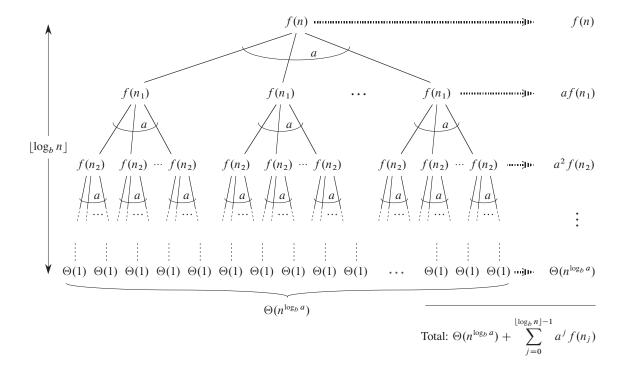

We modify the recursion tree of Figure 4.7 to produce the recursion tree in Figure 4.8. As we go down in the recursion tree, we obtain a sequence of recursive invocations on the arguments

```
n, \lceil n/b \rceil, \lceil \lceil n/b \rceil / b \rceil, \lceil \lceil \lceil n/b \rceil / b \rceil / b \rceil, \vdots
```

Let us denote the j th element in the sequence by  $n_j$ , where

$$n_j = \begin{cases} n & \text{if } j = 0, \\ \lceil n_{j-1}/b \rceil & \text{if } j > 0. \end{cases}$$

$$(4.27)$$

**Figure 4.8** The recursion tree generated by  $T(n) = aT(\lceil n/b \rceil) + f(n)$ . The recursive argument  $n_j$  is given by equation (4.27).

Our first goal is to determine the depth k such that  $n_k$  is a constant. Using the inequality  $\lceil x \rceil \leq x+1$ , we obtain

$$n_0 \le n$$
,  
 $n_1 \le \frac{n}{b} + 1$ ,  
 $n_2 \le \frac{n}{b^2} + \frac{1}{b} + 1$ ,  
 $n_3 \le \frac{n}{b^3} + \frac{1}{b^2} + \frac{1}{b} + 1$ ,  
 $\vdots$ 

In general, we have

$$n_{j} \leq \frac{n}{b^{j}} + \sum_{i=0}^{j-1} \frac{1}{b^{i}}$$

$$< \frac{n}{b^{j}} + \sum_{i=0}^{\infty} \frac{1}{b^{i}}$$

$$= \frac{n}{b^{j}} + \frac{b}{b-1}.$$

Letting  $j = \lfloor \log_b n \rfloor$ , we obtain

$$n_{\lfloor \log_b n \rfloor} < \frac{n}{b^{\lfloor \log_b n \rfloor}} + \frac{b}{b-1}$$

$$< \frac{n}{b^{\log_b n - 1}} + \frac{b}{b-1}$$

$$= \frac{n}{n/b} + \frac{b}{b-1}$$

$$= b + \frac{b}{b-1}$$

$$= O(1),$$

and thus we see that at depth  $\lfloor \log_b n \rfloor$ , the problem size is at most a constant. From Figure 4.8, we see that

$$T(n) = \Theta(n^{\log_b a}) + \sum_{j=0}^{\lfloor \log_b n \rfloor - 1} a^j f(n_j),$$
(4.28)

which is much the same as equation (4.21), except that n is an arbitrary integer and not restricted to be an exact power of b.

We can now evaluate the summation

$$g(n) = \sum_{j=0}^{\lfloor \log_b n \rfloor - 1} a^j f(n_j)$$
 (4.29)

from equation (4.28) in a manner analogous to the proof of Lemma 4.3. Beginning with case 3, if  $af(\lceil n/b \rceil) \leq cf(n)$  for n > b+b/(b-1), where c < 1 is a constant, then it follows that  $a^j f(n_j) \leq c^j f(n)$ . Therefore, we can evaluate the sum in equation (4.29) just as in Lemma 4.3. For case 2, we have  $f(n) = \Theta(n^{\log_b a})$ . If we can show that  $f(n_j) = O(n^{\log_b a}/a^j) = O((n/b^j)^{\log_b a})$ , then the proof for case 2 of Lemma 4.3 will go through. Observe that  $j \leq \lfloor \log_b n \rfloor$  implies  $b^j/n \leq 1$ . The bound  $f(n) = O(n^{\log_b a})$  implies that there exists a constant c > 0 such that for all sufficiently large  $n_j$ ,

$$f(n_{j}) \leq c \left(\frac{n}{b^{j}} + \frac{b}{b-1}\right)^{\log_{b} a}$$

$$= c \left(\frac{n}{b^{j}} \left(1 + \frac{b^{j}}{n} \cdot \frac{b}{b-1}\right)\right)^{\log_{b} a}$$

$$= c \left(\frac{n^{\log_{b} a}}{a^{j}}\right) \left(1 + \left(\frac{b^{j}}{n} \cdot \frac{b}{b-1}\right)\right)^{\log_{b} a}$$

$$\leq c \left(\frac{n^{\log_{b} a}}{a^{j}}\right) \left(1 + \frac{b}{b-1}\right)^{\log_{b} a}$$

$$= O\left(\frac{n^{\log_{b} a}}{a^{j}}\right),$$

since  $c(1+b/(b-1))^{\log_b a}$  is a constant. Thus, we have proved case 2. The proof of case 1 is almost identical. The key is to prove the bound  $f(n_j) = O(n^{\log_b a - \epsilon})$ , which is similar to the corresponding proof of case 2, though the algebra is more intricate.

We have now proved the upper bounds in the master theorem for all integers n. The proof of the lower bounds is similar.

#### **Exercises**

#### 4.6-1 \*

Give a simple and exact expression for  $n_j$  in equation (4.27) for the case in which b is a positive integer instead of an arbitrary real number.

#### 4.6-2 \*

Show that if  $f(n) = \Theta(n^{\log_b a} \lg^k n)$ , where  $k \ge 0$ , then the master recurrence has solution  $T(n) = \Theta(n^{\log_b a} \lg^{k+1} n)$ . For simplicity, confine your analysis to exact powers of b.

## 4.6-3 \*

Show that case 3 of the master theorem is overstated, in the sense that the regularity condition  $af(n/b) \le cf(n)$  for some constant c < 1 implies that there exists a constant  $\epsilon > 0$  such that  $f(n) = \Omega(n^{\log_b a + \epsilon})$ .
